

AR LEAKAGE AUDIT

Power BI Dashboard — Technical & Analytical Documentation

Prepared by: **Sumesh Achary**

Date: June 2026

4 Pages | 16 Visuals | 6 DAX Measures | 3 Synced Slicers

TABLE OF CONTENTS

1. **Dashboard Purpose & Audience**
2. **Data Model & DAX Measures**
3. **How to Read This Dashboard**
4. **Page 1 — Executive Overview**
5. **Page 2 — Aging & Risk**
6. **Page 3 — Sales & Segment Performance**
7. **Page 4 — Regional Intelligence**
8. **Data Limitations & Honest Caveats**
9. **Cross-Page Synthesis & Quantified Recommendations**
10. **Interview Preparation — Anticipated Questions**

1. DASHBOARD PURPOSE & AUDIENCE

This Power BI dashboard operationalises the SQL findings from the AR Leakage Audit into an interactive, self-service tool. While the SQL report answers fixed business questions, this dashboard allows a Finance leader, Collections Manager, or Sales Head to slice the same ₹8.17 Crore invoice base by date, payment status, or customer segment in real time — without writing a single query.

Page	Primary Audience	Core Question Answered
Executive Overview	CFO / Finance Director	Are we healthy overall? Are we improving or declining?
Aging & Risk	Collections Manager	Where exactly is the money stuck, and how urgent is it?
Sales & Segment Performance	Sales Director / Controller	Who owns this risk — which reps, segments, dispute types?
Regional Intelligence	Regional Finance Heads	Which geography needs different credit policy?

2. DATA MODEL & DAX MEASURES

The dashboard runs on a single flat table (AR_Clean_Data, 500 rows) produced by the Excel Power Query pipeline. Six DAX measures power every KPI card, chart axis, and conditional format across all four pages.

Measure	DAX Logic	Used In
Total Billed	SUM(Invoice_Amount)	P1 KPI card, all segment/region bars
Total Collected	SUM(Amount_Paid)	P1 KPI card, regional scorecard
Total Outstanding	SUM(Outstanding_Amount)	P1, P2, P3, P4 — used in nearly every visual
Collection Efficiency %	DIVIDE(SUM(Amount_Paid), SUM(Invoice_Amount), 0)	P1 KPI card, trend line, P4 scorecard
Avg DSO	AVERAGEX over Paid/Late_Paid rows of Days_To_Pay	P1 KPI card, P4 regional DSO line
Overdue Count	COUNTROWS filtered to Payment_Status = Overdue	Supporting measure for cards and tooltips

Key design decision: Collection Efficiency % is stored as a true decimal ratio (0.7259) with Percentage number-formatting applied at display level — not pre-multiplied by 100 in the DAX itself. This is best practice: it keeps the underlying value mathematically correct for any further calculations (e.g. variance analysis) while still rendering as **72.59%** on every card and axis. every visual

3. HOW TO READ THIS DASHBOARD

Every page shares the same three slicers at the top — Invoice Date, Payment Status, and Customer Segment — so a user can filter once and watch all four pages update in sync, thanks to Power BI's page navigation buttons retaining slicer state.

Color	Meaning Across Dashboard
Dark Red	Critical — 90+ days overdue, highest financial risk
Red / Orange	High priority — disputed or significantly overdue
Green	Healthy — paid, low-risk, or within 0-30 day window
Grey	Neutral / no action needed (e.g. None priority bucket)
Dark Blue gradient (Matrix)	Heatmap intensity — darker = higher invoice concentration

Navigation: Four buttons (Executive Overview, Aging & Risk, Sales & Segment Performance, Regional Intelligence) appear at the top of every page. The active page is highlighted in black. Clicking any button jumps instantly to that page while preserving all active slicer selections.

4. PAGE 1 — EXECUTIVE OVERVIEW

The CFO's first stop. Four KPI cards establish the headline numbers, followed by a status breakdown, a segment risk bar, and a 17-month efficiency trend against a 90% target line.

Visual 1 — KPI Cards (×4)

Type: Card | Fields: Total Billed, Total Outstanding, Avg Collection Efficiency, Avg DSO

Total Billed stands at ₹81.74M (₹8.17 Cr) across 18 months. Total Outstanding is ₹22.41M (₹2.24 Cr) — 27.4% of everything billed has not been collected. Average Collection Efficiency of 72.59% sits 17+ points below the 90% industry benchmark. Average DSO of 30.78 days is marginally above the 30-day target, indicating the business is, on average, just at the edge of acceptable but with high variance underneath.

Visual 2 — Invoice Distribution by Status

Type: Donut Chart | Fields: Legend: Payment_Status | Values: Count of Invoice_ID

42% of invoices (210) are cleanly Paid and 24% (120) are Late_Paid — together a 66% core that eventually settles. The remaining third splits across Overdue (16%, 80 invoices), Partial (12%, 60), and Disputed (6%, 30) — the three categories driving the entire ₹22.41M outstanding figure.

Visual 3 — Total Outstanding by Customer Segment

Type: Bar Chart | Fields: Y-axis: Customer_Segment | X-axis: Total Outstanding measure

Enterprise customers alone account for ₹16.3M of the ₹22.41M total outstanding — roughly 73% of all locked cash sits with the segment that should, in theory, have the strongest credit discipline. Mid-Market (₹4.7M), SME (₹1.2M) and Retail (₹0.2M) trail far behind in absolute terms.

Visual 4 — Monthly Collection Efficiency Trend

Type: Line Chart + Constant Line | Fields: X-axis: Invoice_Date (Month) | Y-axis: Collection Efficiency % | Constant line at 90%

The trend line never once touches the 90% target line across the full 17-month window. It peaks near 84-87% around March and November but dips below 65% in January, May, and August — a clear seasonal volatility pattern rather than steady improvement.

■ Insight

Enterprise carries 73% of outstanding value on only 70 of 500 invoices (14% of volume) — this is a concentration problem, not a volume problem.

Separately, the efficiency dip in January/May/August (visible on the trend line) is a pattern worth testing against invoice issuance volume in the preceding month — Indian B2B billing often spikes at fiscal quarter-ends, and a surge in invoices raised in Q-end month could mechanically depress next month's efficiency ratio simply because more invoices are still within their 30-day window. This is a hypothesis the raw data supports investigating further, not yet a confirmed cause.

■ Business Action

Recovering just the Top 10 accounts shown on Page 2 (₹1.66 Cr, which is 74% of all outstanding) would lift Collection Efficiency from 72.59% to approximately **92.9%** — a +20-point swing from fixing 10 relationships out of 80 customers. This single number should anchor the entire collections strategy: this is fundamentally a concentrated, not distributed, problem.

Note on methodology: the Top 10 recovery calculation above assumes full collection of all 10 accounts' outstanding balances and holds Total Billed constant — it is a best-case ceiling, not a guaranteed forecast.

5. PAGE 2 — AGING & RISK

The Collections Manager's working page. Combines an aging pyramid, a dedicated 90+ day risk card, a ranked customer table with in-cell heat bars, and a recovery priority breakdown.

Visual 1 — AR Aging Pyramid

Type: Funnel Chart | Fields: Group: Aging_Bucket | Values: Total Outstanding

90+ Days holds ₹13.27M versus ₹9.14M in 0-30 Days. No invoices fall into the 31-60 or 61-90 day windows (see Section 8 — Data Limitations) — every overdue invoice in this dataset is either fresh or severely aged, with nothing in between.

Visual 2 — 90+ Days At Risk

Type: Card with visual-level filter | Fields: Total Outstanding measure | Filter: Aging_Bucket = 90+ Days

■13.27M sits across 80 invoices in the critical bucket. At this aging stage, standard follow-up calls have largely failed; this figure represents the realistic write-off exposure the CFO needs visibility on for provisioning.

Visual 3 — Top 10 High Risk Customers

Type: Table with in-cell heat bars | Fields: Customer_Name, Customer_Segment, Region, Total_Outstanding, Overdue_Count

All top 10 are Mumbai-based, and 9 of 10 are Enterprise segment. Aggarwal Spices Trading (₹33.4L) and Tandon Auto Parts (₹31.0L) top the list. The heat-bar shading makes the severity hierarchy immediately scannable without reading every number.

Visual 4 — Invoices by Recovery Priority

Type: Bar Chart | Fields: Y-axis: Recovery_Priority | X-axis: Count of Invoice_ID

330 invoices need no action (None), 80 are Critical, 60 are Low-Monitor, and 30 are High-Legal Review. Note: 'Medium-Follow Up' and 'High-Manager Call' categories do not appear because zero invoices fall in the 31-90 day aging range — a genuine data characteristic rather than a chart error.

■ Insight

The complete absence of invoices in the 31-90 day aging window suggests there is no effective mid-stage collections process. Invoices appear to either get caught early (0-30 days) or fall through the cracks entirely until they're severely overdue (90+).

■ Business Action

Introduce a structured 30-60-90 day escalation ladder with mandatory checkpoints. Without intervention at day 30-45, invoices are currently sliding straight to critical status with no intermediate recovery attempt.

6. PAGE 3 — SALES & SEGMENT PERFORMANCE

Accountability page connecting AR outcomes back to the people and processes that create them — sales reps, dispute root causes, segment-level status mix, and an invoice-level risk scatter.

Visual 1 — Outstanding AR by Sales Rep

Type: Bar Chart with color gradient | Fields: Y-axis: Sales_Rep | X-axis: Total Outstanding | Color: Gradient (green→red) on value

Amit Verma (₹4.7M) and Priya Sharma (₹3.9M) carry the heaviest overdue portfolios — together over ₹8.6M, nearly 39% of total outstanding from just 2 of 8 reps. Karan Mehta, by contrast, holds only ₹0.62M — the gradient color makes this contrast immediately visible without reading exact figures.

Visual 2 — Dispute Root Cause Analysis

Type: Bar Chart | Fields: Y-axis: Dispute_Reason | X-axis: Count of Invoice_ID | Filter: Dispute_Flag = Yes

Contract Disagreement and Quality Issue are tied as the top dispute drivers (7 cases each), followed by Goods Not Received and Price Mismatch (6 each). These four reasons account for 26 of 30 total disputes — concentrated, addressable root causes rather than random one-offs.

Visual 3 — Invoice Status by Segment (Matrix)

Type: Matrix with heatmap formatting | Fields: Rows: Customer_Segment | Columns: Payment_Status | Values: Count, color-scaled

SME has the highest invoice volume (180) and the darkest 'Paid' cell (74), confirming small accounts transact more frequently. Mid-Market's Paid count (55) is its strongest cell. Enterprise has the lowest volume (70) but, as Page 1 showed, the highest outstanding value — a classic low-volume, high-value risk profile.

Visual 4 — Risk Matrix — Invoice Value vs Days Overdue

Type: Scatter Chart | Fields: X-axis: Invoice_Amount | Y-axis: Days_Overdue | Legend: Customer_Segment | Details: Invoice_ID

Enterprise dots (light blue) spread across the highest invoice values (₹0.5M–₹1.5M+) with overdue days ranging 400-850 — the most dangerous combination on the chart. SME and Retail dots cluster tightly at low invoice values but still show overdue ranges up to 1000 days, proving small-ticket invoices can be neglected just as long as large ones.

■ Insight

AR risk is not evenly distributed across the sales team — two reps account for nearly 40% of overdue value. Disputes cluster around four specific, fixable root causes rather than being random noise.

■ Business Action

Make Amit Verma and Priya Sharma's accounts the subject of a joint Sales-Finance review this month. Fix Contract Disagreement and Quality Issue disputes at the source by mandating clearer Scope-of-Work documentation before invoicing.

7. PAGE 4 — REGIONAL INTELLIGENCE

Geography-based view for regional finance heads — outstanding by region, a map visualisation, a DSO-by-region trend, and a full regional scorecard table.

Visual 1 — Outstanding Amount by Region

Type: Bar Chart | Fields: Y-axis: Region | X-axis: Total Outstanding measure

Mumbai dominates with ₹16.3M outstanding — more than 5x the next closest region (Pune at ₹2.8M). This mirrors Page 1’s segment finding: Mumbai is where most Enterprise customers are based, so the regional and segment risk stories are really the same underlying concentration.

Visual 2 — Geographic AR Risk Distribution

Type: Map Visual | Fields: Location: Region | Bubble Size: Total Outstanding

The map bubble over Mumbai dwarfs every other Indian city shown, giving an instant geographic confirmation of where collections effort should concentrate physically — useful if planning in-person visits or assigning region-based collection agents.

Visual 3 — Average DSO by Region

Type: Line Chart | Fields: X-axis: Region (sorted) | Y-axis: Avg DSO measure

Kolkata has the worst DSO at 35.2 days, while Mumbai shows the best DSO at 26.37 days — despite Mumbai also holding the highest absolute outstanding value on the chart to its left. This looks contradictory at first glance and is resolved explicitly below.

Visual 4 — Regional Performance Scorecard

Type: Table sorted by Collection Efficiency | Fields: Region, Total_Billed, Total_Outstanding, Collection Efficiency %, Avg_DSO

Bangalore leads at 82.80% collection efficiency; Kolkata trails at 62.75% — a 20-point gap between best and worst region. Mumbai sits mid-table at 72.21%, almost exactly the company average of 72.59% — confirming Mumbai is large in absolute terms but not proportionally worse-behaved than the portfolio as a whole.

Resolving the Mumbai Paradox: Why Best DSO and Worst Outstanding Coexist

The Avg DSO measure is deliberately built as: `AVERAGEX(FILTER(Payment_Status IN {Paid, Late_Paid}), Days_To_Pay)`. By construction, this formula only ever looks at invoices that **did** eventually get paid — it structurally excludes every Overdue, Partial, and Disputed invoice. DSO and Outstanding Amount are therefore not measuring the same population of invoices; they are two different lenses on the same region.

Metric	What It Measures	Mumbai Value
Avg DSO (26.37 days)	Speed of the invoices that DID get paid	Best in the dataset — Mumbai's healthy invoices
Total Outstanding (■16.3M)	Total stuck in invoices that have NOT been paid	Worst in absolute terms — driven by ~9-10 chronic
Outstanding as % of Mumbai's own billing	27.87% of everything billed in Mumbai is unpaid	In line with company average (27.4%) — not actual

Conclusion: Mumbai does not have a payment-speed problem — it has a concentration problem, identical to the Enterprise-segment finding on Page 1 (this is the same root cause appearing twice from two different angles, which strengthens confidence that it is real and not a fluke of one chart's filtering). Kolkata and Ahmedabad, by contrast, show weak metrics on every cut — they have an actual behavioural payment problem across their customer base, not a concentration issue.

■ Insight

Two regions need attention for entirely different reasons: Mumbai's issue is 9-10 specific accounts (a collections task), while Kolkata/Ahmedabad's issue is portfolio-wide behaviour (a credit policy task). Conflating them into one 'regional risk' response would misallocate effort.

■ Business Action

Mumbai: assign the Top 10 table (Page 2) to named account owners — no regional policy change needed. Kolkata & Ahmedabad: tighten terms for ALL customers (e.g. shorten credit period from 30 to 15 days, or require partial advance) since the weakness is structural, not isolated to a few accounts.

8. DATA LIMITATIONS & HONEST CAVEATS

A strong analytics portfolio acknowledges what the data does NOT show, not just what it does. These limitations were discovered during dashboard construction and are disclosed transparently rather than hidden:

Empty mid-range aging buckets

No invoices fall into the 31-60 or 61-90 day windows. This is a characteristic of how the synthetic dataset's Overdue invoices were dated (either freshly overdue or very old), not a real-world guarantee — in a production dataset, these buckets would typically be populated.

Days_Overdue not tracked for Partial/Disputed statuses

The aging calculation in Power Query was built specifically for the 'Overdue' status. Partial and Disputed invoices show Days_Overdue = 0 even though they are genuinely outstanding — meaning the scatter chart on Page 3 undercounts true aging risk for these two categories.

Synthetic, not live, data

All 500 invoices were constructed to realistically mirror AR patterns observed in real Finance/AR experience, but are not drawn from an actual company's transaction system. Numbers and trends are illustrative of the analytical method, not a real business's financial position.

Map visual approximates city centroids

Power BI's built-in geocoding places each region at its city centre point; it does not reflect customer-specific addresses, so the bubble size is accurate but its exact pin location is a city-level estimate.

9. CROSS-PAGE SYNTHESIS & QUANTIFIED RECOMMENDATIONS

Reading all four pages together reveals one consistent story, confirmed independently three separate ways: by segment (Page 1), by named customer (Page 2), and by region (Page 4). **A small, identifiable concentration of Enterprise/Mumbai accounts — not the customer base broadly — is responsible for the majority of AR risk.** The fact that three unrelated cuts of the same 500 rows point to the same handful of accounts is what makes this finding trustworthy rather than coincidental.

Scenario Modelling — What Moves the 72.59% Number

Scenario	Amount Recovered	New Outstanding	New Efficiency	Point Gain
Current state	—	₹22.41M	72.59%	—
Recover 0-30 Day bucket only (realistic 30-day target)	₹9.14M	₹13.27M	83.77%	+11.18 pts
Recover Top 10 accounts fully (Page 2 table)	₹16.60M	₹5.81M	92.89%	+20.31 pts

Both scenarios assume Total Billed (₹81.74M) stays constant and recovered amounts convert fully from Outstanding to Collected — these are best-case ceilings to set targets against, not forecasts of what will happen.

The Top 10 scenario delivers nearly double the efficiency gain of the aging-bucket scenario, despite touching only 10 of 500 invoices (2% of volume). This is the single most important number in the entire analysis: **it tells the business exactly where to spend its limited collections bandwidth for maximum return.**

The Five-Point Action Plan, in Priority Order:

1. Assign named owners to the Top 10 accounts this week

Highest leverage action available: ₹1.66 Cr (74% of all outstanding) sits with 10 customers. This alone is worth +20.3 efficiency points — more than any other single intervention modelled above.

2. Build the missing 30-60-90 day escalation ladder

Page 2's aging pyramid shows zero invoices in the 31-90 day window — invoices currently jump straight from healthy to critical with no intermediate checkpoint. A day-30/45/60 trigger system would prevent future invoices from following the same path as the current 90+ Day bucket (₹13.27M).

3. Differentiate regional policy by mechanism, not magnitude

Mumbai needs account-level collections (a people problem, 9-10 names). Kolkata and Ahmedabad need policy-level change — shorter credit terms for everyone — because their weakness shows up on every metric (DSO, efficiency, outstanding %), not just one.

4. Pair sales accountability with the four named dispute causes

Amit Verma and Priya Sharma hold 39% of overdue value between two reps; Contract Disagreement and Quality Issue cause the most disputes. Link commission to collected (not billed) revenue, and mandate Scope-of-Work sign-off before invoicing for Consulting engagements specifically.

5. Close the Days_Overdue measurement gap before this goes to production

Partial and Disputed invoices currently show Days_Overdue = 0, understating their true age. Extending this calculation is a data-model fix, not a business-process fix — but it must happen before any of the above targets are tracked against real incoming data, or the dashboard will quietly under-report risk in those two categories.
